**ADVERSE CHILDHOOD EXPERIENCES (ACEs)**

The ACE Study confirms, with scientific evidence, that adversity during development increases the risk of physical, mental, and behavioral problems later in life. The ACE Study and subsequent research indicate that ACEs are the leading cause of health and social problems in our nation – the most powerful determinant of the public’s health.

Brain development is experience-dependent and sequential. Repeated exposure to life events that cause our brains to release stress chemicals, like cortisol, can become “toxic” to our developing brain cells. Toxic stress can effect brain interaction with body systems and lead to disease, disability, and social/relationship problems throughout the life course. But childhood times are also windows of opportunity for building resilience – the developing brain is sensitive to all kinds of experience, “toxic” or positive! (Source: http://www.aceinterface.com/)

### The ACEs Study: Drs. Felliti and Anda
An ongoing collaboration of the CDC and Kaiser Permanente

The ACEs Study is the largest of its kind, with over 17,000 participants from the Kaiser Health Plan in San Diego, CA. Participants provided detailed information about childhood experiences of abuse, neglect, and family dysfunction. The ACE Study considered 10 categories of childhood adversity, and the findings include:

- ACEs are common across all categories.
- ACEs are interrelated – 87% with 1 ACE have another.
- ACE accumulation is stored in our bodies, leading to mental, physical, & behavioral health problems throughout our life course.
- Preventing ACEs for the next generation can have a profound impact on the prevalence of most major public health issues in our community, from homelessness, suicide, depression, & drug use to COPD, heart disease, & liver disease!

### ACEs, Related Stressors, and Developmental Delay

Brain research tells us the amount of maltreatment (risk factors) we experience during the first 3 years of life, things like - physical, emotional and sexual abuse, neglect, witnessing domestic violence, divorce or abandonment, growing up in a home with a caregiver who has mental health or substance abuse issues, homelessness and poverty - can have profound impacts on how our brain processes certain information. Maltreatment can effect our brain’s ability to focus or pay attention, how we understand social cues and language, our ability to regulate our hormones, mood, and even our heartbeat.

Key Findings: ACEs are strong predictors of health risks & disease in adolescence and beyond

*from the original ACEs Study

ACEs rarely occur in isolation – but rather come in groups and have a cumulative stressor effect. Of persons reporting at least one ACE, 87% reported at least one other ACE. 70% reported 2 or more others and more than half had 3 or more additional ACEs!

Creating Resilience

As compelling as the predictive power of ACEs is, many people do well despite exposure to adversity. As articulated by former president of the American Academy of Pediatrics, Dr. Robert Block, “Rather than saying to parents, ‘You have a problem’, we can say, ‘There are some things going on in your life that are having a tremendous effect on you and your child. Let’s see if we can figure out a way to help and make that situation better.”

We can help children by:
- Gaining an understanding of ACEs in their life
- Creating environments where they are safe, emotionally and physically
- Helping them identify feelings and control emotions
- Creating protective factors at home, in schools and in communities

Protective Factors:
- Parental resilience and supportive relationships
- Nurturing relationships with caring adults
- Supportive social connections and peer relationships
- Concrete supports for basic needs (food, housing, health care, etc.)
- Knowledge of parenting and child development
- Social emotional competence
